

Tables: one per figure

Table 1: **2010 Characteristics by Tract Treatment Status** This table presents summary statistics for 2010 PRCS (ACS 2006–2010 5-year) tract characteristics — all pre-determined relative to Act 22 (January 2012) — separated by tracts that ever receive an identified decree-era investor purchase (treated) and tracts that never do. Column (7) reports the raw mean difference between treated and never-treated tracts and column (8) the difference after residualizing out municipio (county) fixed effects, with heteroskedasticity-robust p -values in parentheses. Dollar variables in 2010 dollars; shares in [0,1]. 2010 tracts are mapped to 2020 boundaries by largest land overlap, population-weighted. Statistical significance levels are indicated as follows: *** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$.

	Treated Tracts			Never-Treated Tracts			Mean Diff.	Adj. Mean Diff.

Table 2: **Robustness to Last-Sale Censoring: Later Event Cohorts** This table addresses last-sale censoring in the CRIM cadastre, which records only each parcel’s most recent sale: pre-period sales near early events are survivors that never resold, so old transactions are “stale” and progressively selected. Restricting to later events shortens the censoring window. Columns restrict the event set by purchase year; the number of events in each set is reported. Outcome: cell mean log sale price ($\times 100$), near ring (0–250m) vs never-treated control rings. The Treated coefficient is the post–pre effect from a single LP-DiD regression via pre-mean differencing (Dube, Girardi, Jordà and Taylor 2023): dependent variable $\frac{1}{4} \sum_{h=0}^3 y_{t+h} - \frac{1}{4} \sum_{\tau=t-4}^{t-1} y_{\tau}$ on treatment entry with calendar-time effects, clean-control sample; its SE, R^2 and Observations come from that regression. Coefficients are $100 \times \log$ points (shares in pp). SEs clustered by unit (cell/tract). Statistical significance levels are indicated as follows: *** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$.

	All events (2012+)	2018+	2020+	2022+

R-squared	0.154	0.115	0.078	0.055
Calendar-year effects	Yes	Yes	Yes	Yes
Event $\times$ ring cell differencing	Yes	Yes	Yes	Yes
Hedonic controls	No	No	No	No

Table 3: **Tract-level treatment effects are robust to county-year shocks** This table reports Treated coefficients from the paper’s baseline estimator — the pre-mean-differenced LP-DiD (Dube et al. 2023; $H=3$, $k=4$, clean-control sample: newly treated tracts at onset plus never-treated tracts) — under two specifications per outcome: (1) calendar-year effects; (2) county×year effects, so identification is within municipio-year. Tract fixed effects are subsumed by the long-differencing. Panel A: tract log price (Red Atlas, count-weighted annual mean) and log mean purchase-borrower income (HMDA, 2012–2024), both scaled by 100. Panel B: purchase origination counts by borrower ethnicity as $100 \times \text{asinh}$ (Poisson does not compose with pre-mean differencing; the Poisson event studies appear in the figures). Robust standard errors are clustered at the tract level and reported in parentheses. Statistical significance levels are indicated as follows: *** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$.

Panel A: prices and borrower income				
	<i>100 × Log(Price)</i>		<i>100 × Log(Borrower Income)</i>	
	(1)	(2)	(1)	(2)

County-year effects	No	Yes	No	Yes

Table 4: **Price Effects by Investor Concentration: Ring and Tract Designs** This table reports LP-DiD price effects by investor concentration under both designs, on the tract design’s dose convention. Columns (1)-(2): ring design, events split by total identified purchases within 1km of the event (the event itself included); each group’s near rings (0–250m) vs never-treated control rings, cell-level annual LP-DiD. Columns (3)-(4): tract design, treated tracts split by identified purchases in the tract, each group vs never-treated tracts. The Treated coefficient is the post–pre effect from the single pre-mean-differenced LP-DiD regression (Dube et al. 2023), whose SE, R-squared, and Observations are reported. All outcomes $100 \times \log$ price; SEs clustered by cell (ring) or tract. Statistical significance levels are indicated as follows: *** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$.

	<i>Ring design</i>		<i>Tract design</i>	
	1–4 purch.	5+ purch.	1–4 purch.	5+ purch.
	(1)	(2)	(3)	(4)
Treated	-2.74 (3.45)	6.41*** (1.50)	4.13*** (1.59)	16.30*** (2.54)
Observations	2,854	9,525	11,670	11,476

Calendar-year effects	Yes	Yes	Yes	Yes
Never-treated controls	Yes	Yes	Yes	Yes

Table 5: **Institutional Deployment DiD: Pooled Effects, Post Window Capped at $t = 2$** This table reports the pooled institutional-deployment DiD with the post window capped at $t=2$: the Treated coefficient is the post-pre effect from the pre-mean-differenced LP-DiD ($\frac{1}{3} \sum_{h=0}^2 y_{t+h} - \frac{1}{4} \sum_{\tau=t-4}^{t-1} y_{\tau}$ on treatment entry, calendar-year effects, clean-control sample, SEs clustered by tract). Outcome: portfolio-cluster purchases per tract-year (buyer name or rolled-up mailing address holding 10+ parcels; banks excluded). Columns: (1) baseline counts; (2) dropping the five tracts whose onset-year single-building acquisitions are 88% of year-0 portfolio purchases; (3) restricting to tracts first treated 2015+ (a cohort cut avoiding the 2014 Cobián Plaza acquisition non-selectively); (4) the extensive margin, an indicator for any portfolio purchase; (5) counts capped at 3. The small positives in (4)-(5) are threshold effects of the island-wide entity trend in high-volume markets (null under Poisson) and are bounded at ≈ 0.1 purchases per tract-year. Statistical significance levels are indicated as follows: *** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$.

	Baseline (1)	Drop 5 bulk tracts (2)	Events 2015+ (3)	1{any purchase} (4)	Capped at 3 (5)

Table 30: **Observed tract effects vs ring-implied predictions (fig. T4)** Observed: LP-DiD pooled post (group vs never-treated tracts), SEs clustered by tract. Predictions: stock-value-weighted distance-gradient effects over each treated tract’s parcels, averaged within group. Gap = observed minus central prediction. $100 \times \log$ points. Statistical significance levels are indicated as follows: *** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$.

Group	Observed	Pred. (central)	Pred. (conserv.)	Gap
All treated	7.55*** (1.81)	5.76	5.13	1.79
1–4 purchases	3.76* (2.12)	5.37	4.56	-1.61
5+ purchases	18.31*** (2.88)	7.45	7.57	10.86

Table 31: **Investor Purchases vs Placebo Luxury Purchases** Placebo events are 1,500 purchases by individual non-investor buyers in the investor price band, drawn from the same micro-areas and more than three years from any real event; both series use far rings matched at 400–750m. Columns (1)-(2): cell mean log sale price ($\times 100$). Columns (3)-(4): net Hispanic-to-non-Hispanic ownership conversion per classified sale (percentage points; $1\{\text{Hisp. seller, non-Hisp. buyer}\} - 1\{\text{non-Hisp. seller, Hisp. buyer}\}$). Responses unique to investor purchases rule out generic luxury-transaction effects on both prices and neighborhood ownership composition. The Treated coefficient is the post–pre effect from a single LP-DiD regression via pre-mean differencing (Dube, Girardi, Jordà and Taylor 2023): dependent variable $\frac{1}{4} \sum_{h=0}^3 y_{t+h} - \frac{1}{4} \sum_{\tau=t-4}^{t-1} y_{\tau}$ on treatment entry with calendar-time effects, clean-control sample; its SE, R^2 and Observations come from that regression. Coefficients are $100 \times \log$ points (shares in pp). SEs clustered by unit (cell/tract). Statistical significance levels are indicated as follows: *** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$.

Table 32: **Ring-design treatment effects: county-year shocks and house-characteristic controls** This table subjects the ring design’s estimates to a specification ladder, using the paper’s baseline estimator throughout: the pre-mean-differenced LP-DiD on the event×ring cell panel ($H=3$, $k=4$; clean-control sample: newly treated near cells at onset plus never-treated cells; specification (1) reproduces the baseline table exactly). Specifications: (1) calendar-year effects; (2) county×year effects (the county is the event’s municipio), so identification is within municipio-year; (3) adds house-characteristic controls from the transaction data — cell-year means of log assessed structure value, log lot size (cabida), sub-unit share, and vacant-land share, each pre-mean differenced exactly like the outcome — so the column (3) Treated coefficient is a constant-composition price effect. Cell fixed effects are subsumed by the long-differencing. Outcomes: cell mean log sale price ($\times 100$) and the net Hispanic-to-non-Hispanic ownership conversion rate per classified sale (percentage points). Robust standard errors are clustered at the cell level and reported in parentheses. Statistical significance levels are indicated as follows: *** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$.

Table 33: **Summary Statistics** This table presents summary statistics for the paper’s main samples. Panel A: market sales within 1km of an identified decree-era investor purchase (ring design estimation sample: gap ring, junk/nominal prices, and investor-parcel sales excluded; events 2012+); name-classification indicators are defined over sales whose parties’ surnames classify. Panel B: Red Atlas tract×year panel (transaction-count-weighted annual mean prices); identified purchases reported over the 235 treated tracts. Panel C: HMDA tract×year panel of originated first-lien owner-occupied 1–4 family purchases, 2012–2024. Panel D: 2010 PRCS tract characteristics (2020 boundaries, population-weighted).
